

Introduction to Climate Change

Prof. Dr. Anisul Haque
Director,
Institute of Water and Flood Management, BUET

Our Earth and its Climate

A planet's climate is decided by

- Mass,
- Distance from the sun
- Composition of its atmosphere.

We are capable of changing it significantly.

Atmospheric Composition

- 78% nitrogen, 21% oxygen, and 1% other gases.
- Carbon dioxide accounts for just 0.03 - 0.04%.
- Water vapor 0 to 2%

Green House Gases

An essential enemy!!

- CO₂ and some other minor gases
 1. Absorb some of the thermal radiation leaving the surface of the earth.
 2. Emit radiation from much higher and colder levels out to space.

- These radiatively active gases are known as greenhouse gases.
 - They act as a **partial blanket** for the **thermal radiation from the surface** which enables it to be **substantially warmer** than it would otherwise be, **analogous to the effect of a greenhouse**.

- Without the greenhouse gases, Earth's average temperature would be roughly **-20°C**.

Global Temperature and Greenhouse gases

Temperature and CO₂ concentration in the atmosphere over the past 400 000 years
(from the Vostok ice core)

Global Temperature..

Long Term Trends and Climate Sensitivity

- There is a strong correlation between carbon dioxide content in the atmosphere and temperature.
- Over the last 400,000 years the Earth's climate has been **unstable**, with very significant temperature changes, going from a warm climate to an ice age in as rapidly as a few decades.
- The climate may be quite sensitive to internal or external climate forcing and feedbacks.

Global Temperature..

Greenhouse Gases : Why Worry?

- **Temperatures** have been **less variable** during the last **10,000 years**.
 - It is **unlikely** that **global mean temperatures** have varied by **more than 1°C** in a **century** during this period.
 - *A possible scenario:* anthropogenic emissions of **Green House Gases (GHGs)** could bring the climate to a state where it reverts to the highly unstable climate of the pre-ice age period.

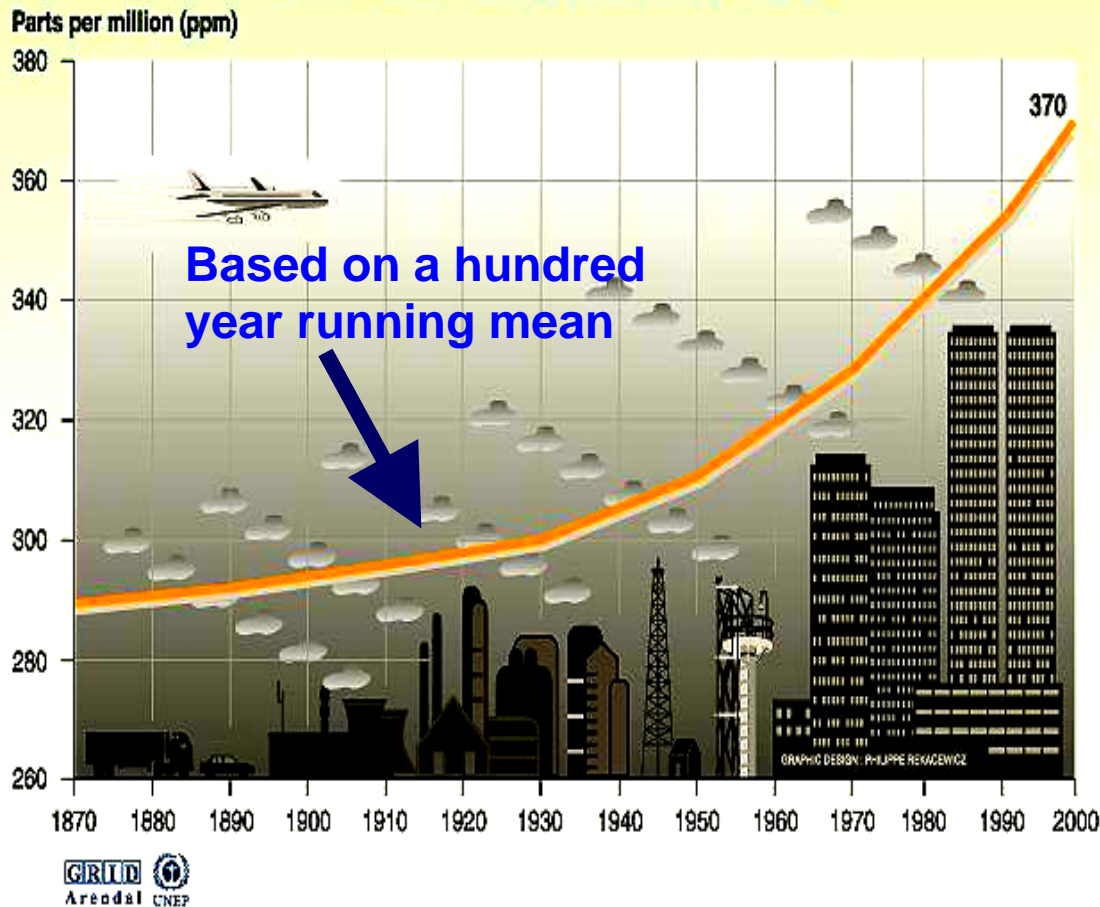

- Rather than a linear evolution, the **climate follows a non-linear path** with sudden and dramatic surprises when GHG levels reach an as-yet unknown trigger point.

Increasing trend of CO₂ the age of idustrialization

Global atmospheric concentration of CO₂

- Pre-industrial concentration 280ppmv
- Present concentration 367ppmv.
- The rapid increase in CO₂ concentrations has been occurring since the onset of industrialization.
- Closely followed the increase in CO₂ emissions from fossil fuels.

(ppmv= parts per million by volume).

Global Surface Temperature

Recent Trends

Source: School of environmental sciences, climatic research unit, university of East Anglia, Norwich, United Kingdom, 1999.

Combined land-surface air and sea surface temperatures (°C) 1861 to 1998, relative to the average temperature between 1961 and 1990.

Increasing Trend of Global Temperature

- The mean global surface temperature has increased by about 0.3 to 0.6°C since the late 19th century.

- By about 0.2 to 0.3°C over the last 40 years, which is the period with most reliable data.

- Recent years have been among the warmest since 1860 – the period for which instrumental records are available.
 - The four warmest years on record since 1860 have all occurred since 1990.

Global Warming → Recent observations

- The warming has been greatest at night over land in the mid-to-high latitudes of the northern hemisphere.
- The warming during the northern winter and spring has been stronger than at other seasons.
- In some areas, primarily over continents, the warming has been several times greater than the global average.
- However, in a few areas, temperatures have actually cooled, e.g., over the southern Mississippi Valley in North America.

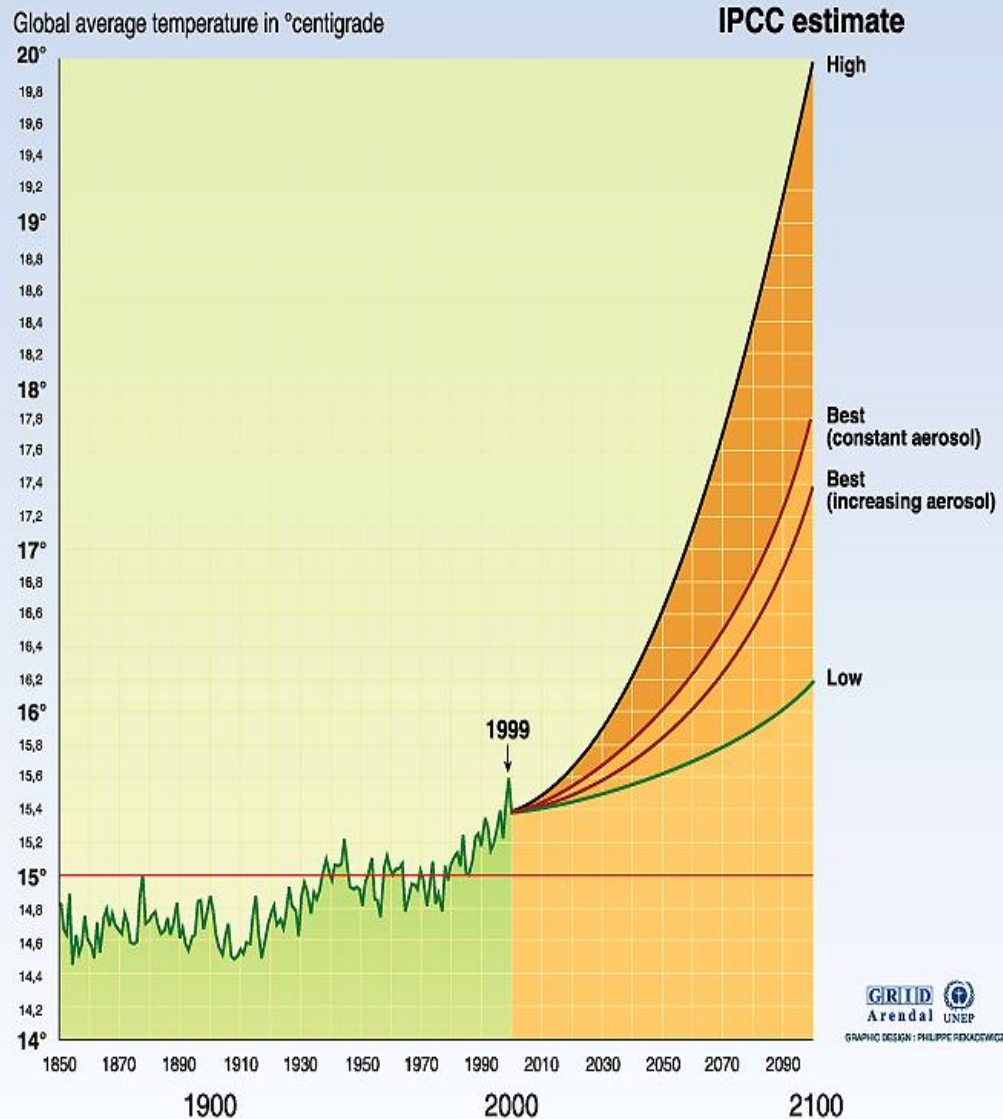

Global temperature increase predictions

IPCC estimates 1 to 5°C increase

□ IPCC stands for Intergovernmental Panel on climate change.

Projected changes in global temperature:
global average 1856-1999 and projection estimates to 2100

Source : Temperatures 1856 - 1999: Climatic Research Unit, University at East Anglia, Norwich UK. Projections: IPCC report 95.

How global warming influences climatic processes

- The air temperature difference drives the atmospheric circulation.
- The temperature of ocean water drives the ocean currents.
- Once the temperature is increased the energy input driving these processes increases.
 - This results speeding up of the processes.
- The moisture holding capacity of air increases
 - Temperature increase results in higher rate of evaporation and transpiration.

Change in Precipitation patterns

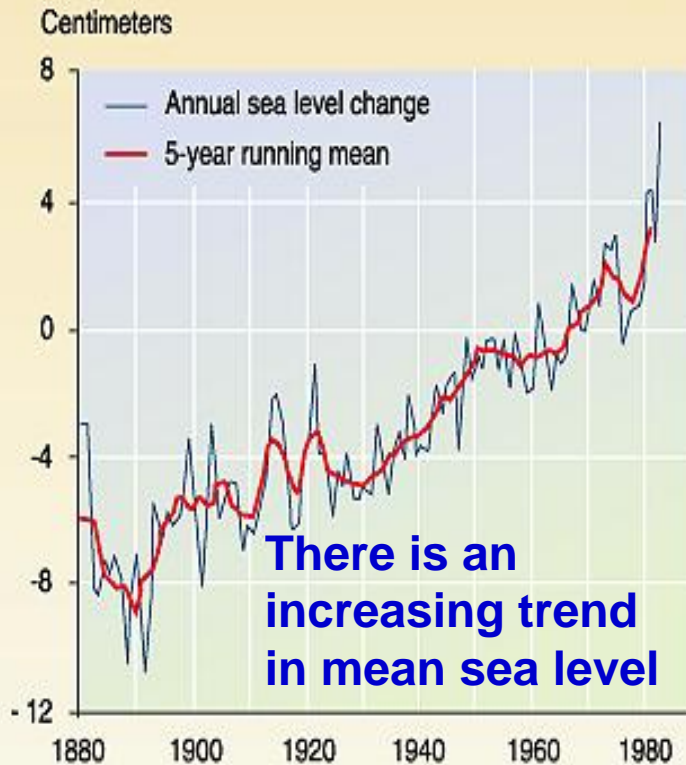

- ❑ Change in global temperature will have a definite effect on the distribution of precipitation.
- ❑ Precipitation has increased over land at high latitudes of the Northern Hemisphere, especially during the cold season.
- ❑ Decrease in precipitation occurred in steps after the 1960s over the subtropics and the tropics from Africa to Indonesia.
- ❑ Precipitation averaged over the Earth's land surface increased from the start of the century up to about 1960, but has decreased since about 1980.

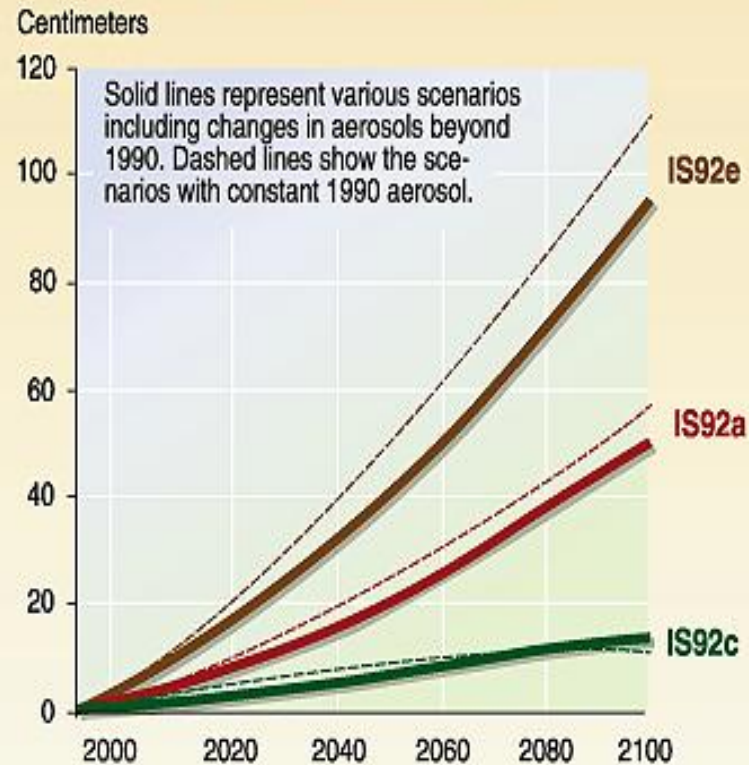

Global Warming → Mean Sea Level rise

Sea level rise due to global warming

Sea level rise over the last century

Sea level rise scenarios for 2100

GRAPHIC DESIGN: PHILIPPE ROKACEWICZ

Source: Climate change 1995, The science of climate change, contribution of working group 1 to the second assessment report of the intergovernmental panel on climate change, UNEP and WMO, Cambridge university press, 1995; Sea level rise over the last century, adapted from Gornitz and Lebedeff, 1987.

Global Warming → Mean Sea Level rise

- ❑ Over the **last 100 years**, the global sea level has risen by about **10 to 25 cm**.
- ❑ It is likely that much of the rise in sea level has been related to the concurrent rise in global temperature over the last 100 years.
- ❑ On this time scale, the warming and the consequent thermal expansion of the oceans may account for about **2-7 cm** of the observed sea level rise, while the observed retreat of glaciers and ice caps may account for about **2-5 cm**.
- ❑ The rate of observed sea level rise suggests that there has been a **net positive contribution** from the huge ice sheets of Greenland and Antarctica,
- ❑ The ice sheets remain a major source of uncertainty in accounting for past changes in sea level because of insufficient data.

Climate Change and Bangladesh Scenario

- ❑ The country is located in the Bengal Basin, a low-lying very flat delta.
- ❑ About 80 per cent of Bangladesh is floodplains with very low mean elevation above the sea level.
- ❑ Differences in the elevation between adjoining ridge tops and depression centers range from
 - ❑ less than 1 meter on tidal floodplains,
 - ❑ 1 to 3 meters on the main river and estuarine floodplains, and
 - ❑ up to 5 to 6 meters in the Sylhet Basin in the north-east.
- ❑ Only in the extreme north-west land elevations exceed 30 meters above the mean sea level.

Climate change and Bangladesh

- The flat topography makes a significant part of Bangladesh vulnerable to sea level change.
 - The active delta and dynamic morphology complicates the reliable estimation of vulnerability of tidal floodplains to sea level rise.
- The net sea level rise would result in
 - Inundation of coastal land
 - Reduced drainage and hence prolonged flooding due to high backwater.
- Higher precipitation within GBM basin would result in greater flood magnitude and frequency.

How much of it do we deserve?

Emissions of CO₂ - selected countries (1995)

GRAPHIC DESIGN : PHILIPPE REKACZEWICZ

Source : International Energy Agency, 1996.

- ❑ Per capita emissions of CO₂ is less than 0.2 ton annually in Bangladesh, compared to 1.6 tons in the developing countries
- ❑ The global average being 4.0 tons annually in the world as a whole.

Before the signing of the Kyoto Protocol
